The history of supernova neutrinos

Prof. John LoSecco
Department of Physics
University of Notre Dame

Supernovae, the largest explosions in the universe, mark the end of nuclear burning for massive stars. This talk traces our understanding of stellar mechanisms from the mid 19'th century to the present. In many cases progress in astrophysics was delayed until future physics discoveries were made. Somewhat surprisingly, the neutrino, a relatively poorly understood elementary particle, plays a critical role in these mechanisms.
